

# Exam on “Functional Properties: Magnetism”

Lecturer: Graeme Blake

Friday January 26, 2018

Martini Plaza

(half of the 09.00 – 12.00 time slot)

Exam drafted by Graeme Blake, exam reviewed by Caspar van der Wal

Name:.....

Student Number: .....

This exam paper contains 3 questions on 6 pages.  
Please answer on the back of the page if you need more space.  
A periodic table is supplied at the end of the paper (page 7).

---

For administrative purposes; do NOT fill the table

	Maximum points	Points scored
Question 1	10	
Question 2	14	
Question 3	11	
Homework	1 point of final score	
<b>Total</b>		

The exam grade for the magnetism part is calculated as  $1 + 9 \times (\text{exam points}/35)$ .  
The final grade for the magnetism part is (exam grade) + (homework grade).

**Final grade:** \_\_\_\_\_

**Question 1 (10 points)**

- a. i. On the left-hand plot below, draw a typical magnetic susceptibility versus temperature curve for a *ferromagnet* with  $T_C = 100$  K. (2 points)
- ii. On the right-hand plot below, draw a typical *inverse* magnetic susceptibility versus temperature curve for an *antiferromagnet* with  $T_N = 50$  K. (2 points)

- b. Propose a suitable order parameter for a paramagnetic to antiferromagnetic phase transition and explain why this order parameter is suitable. (2 points)

- c. Describe how the effective magnetic moment in the *paramagnetic* temperature region (above the ordering temperature of the ferromagnet or antiferromagnet) can be experimentally determined. (2 points)

Name: \_\_\_\_\_ Student number: \_\_\_\_\_

**d.**  $\text{LaBaNiO}_4$ , in which  $\text{Ni}^{3+}$  ( $3d^7$ ) is octahedrally coordinated by oxygen, is a paramagnetic insulator. The effective magnetic moment of Ni is  $\mu_{\text{eff}} = 1.75 \mu_{\text{B}}$  at 100 K but  $\mu_{\text{eff}} = 3.90 \mu_{\text{B}}$  at room temperature. Give a possible explanation for these different values. (2 points)

**Question 2 (14 points)**

**a. i.** Using Hund's rules, determine the ground state of the  $\text{Sm}^{3+}$  cation (electronic configuration  $4f^5$ ). (2 points)

**ii.** Calculate the effective magnetic moment of ground-state  $\text{Sm}^{3+}$ . (The Landé g-value for  $\text{Sm}^{3+}$  is  $g_J = 2/7$ .) (2 points)

**iii.** The measured effective moment of  $\text{Sm}^{3+}$  is  $\mu_{\text{eff}} = 1.74 \mu_{\text{B}}$ . Does this agree with your calculated value? Comment on your answer. (2 points)

c. Consider a metal oxide in which neighbouring transition metal atoms, both octahedrally coordinated by oxygen, each contain one unpaired electron in the  $3d_{z^2}$  orbital. Superexchange can take place via the  $2p_z$  orbital of a bridging oxygen atom in the geometry shown schematically below. Explain why superexchange in this geometry is antiferromagnetic. (2 points)

d.  $\text{LaMnO}_3$  possesses one unpaired electron in its manganese  $3d_{z^2}$  orbital. These orbitals order spatially as shown in the picture below. Explain briefly why this happens. (Here  $\text{Mn}^{3+}$  has electron configuration  $3d^4$  and manganese is octahedrally coordinated by oxygen.) (2 points)

e. The spin associated with one  $\text{Mn}^{3+}$  cation in  $\text{LaMnO}_3$  is shown by the arrow (lower left on the diagram above). Indicate on the picture the directions of the other spins. Is the overall spin ordering in  $\text{LaMnO}_3$  ferromagnetic or antiferromagnetic? (2 points)

Name: \_\_\_\_\_ Student number: \_\_\_\_\_

**f.**  $\text{LaMnO}_3$  is an insulator. When more than 20% of the trivalent  $\text{La}^{3+}$  in  $\text{LaMnO}_3$  is replaced by divalent  $\text{Sr}^{2+}$ , the material becomes metallic. Suggest why. (2 points)

**Question 3 (11 points)**

**a.** When a ferromagnetic material is cooled down through its Curie temperature in the absence of an applied magnetic field, it forms ferromagnetic domains. Explain why these domains spontaneously form. (2 points)

**b.** Sketch a typical magnetization versus applied magnetic field loop for a soft ferromagnet and a hard ferromagnet. Give an example of an application for each type of ferromagnet and explain briefly why its properties are suitable for that application. (4 points)

c. Ferromagnetic nickel has a cubic crystal structure with lattice constant  $3.524 \text{ \AA}$ . There are 0.6 spins per atom in the ferromagnetic state, the exchange constant  $J$  is equal to  $k_B T_C$  where  $T_C = 627 \text{ K}$ , and the easy axis anisotropy is  $K = -0.5 \times 10^4 \text{ J/m}^3$ . Calculate the domain wall thickness (assume Bloch walls). (2 points)  
 (Note:  $k_B = 1.381 \times 10^{-23} \text{ J/K}$ )

d.  $\text{YbMgGaO}_4$  is an insulator and has a crystal structure in which the magnetic  $\text{Yb}^{3+}$  cations ( $S = \frac{1}{2}$ ) are arranged in two-dimensional layers with a triangular pattern as shown below by the blue circles. The sign of  $J$  for the exchange interaction between neighbouring  $\text{Yb}^{3+}$  cations is negative (antiferromagnetic). Discuss what the magnetic properties of  $\text{YbMgGaO}_4$  might be and whether you would expect long-range magnetic ordering to occur in this compound. How could you test your prediction experimentally? (3 points)
