

Thermodynamics and Statistical Physics

Part I – Thermodynamics

Resit

Wednesday, April 12 2023, 15:00-17:00, Aletta Jacobshal

The total number of points that can be reached in this exam is 90.

Final grade = (points/10) + 1.

PROBLEM 1

Score: $a+b+c = 10+10+10=30$

- 1) The pressure in the thermosphere outside the international space station (about 340 km above sea level) is about 10^{-5} Pa and the temperature is about 1100 °C. Estimate the mean free path of an N_2 molecule ($M_{N_2}=28$ g/mol, $d=0.37$ nm) under these conditions **(10 pt)**.
- 2) Express the first law of thermodynamics as an equation and with words. **(10 pt)**
- 3) Explain the concept of thermodynamic “reversibility” for the case of an expanding ideal gas. **(10 pt)**

PROBLEM 2

Score: $a+b+c = 12+12+6=30$

Your apartment had a very old window of area $A = 1.5$ m² with thermal conductance $\frac{\kappa}{L} = 6$ Wm⁻²K⁻¹. This window is replaced by a state of the art double-pane window with $\frac{\kappa}{L} = 1$ Wm⁻²K⁻¹.

- a) Use the thermal diffusion equation in one dimension

$$\frac{\partial T}{\partial t} = D \frac{\partial^2 T}{\partial x^2}$$

To determine a functional form of the temperature profile through the window $T(x)$, with the temperatures T_{outside} and T_{inside} both constant. **(10 pt)**.

- b) Give a functional form for the heat flux through the window using $T(x)$. **(10 pt)**.
- c) How much energy do you save per winter day (24 hours), assuming a constant temperature outside of -5 °C and inside of 20 °C? **(10 pt)**.

PROBLEM 3

Score: $a+b+c+d = 8+8+8+6 = 30$

A Carnot cycle describes a hypothetical engine which connects two reservoirs and undergoes the following *reversible* processes:

- i. isothermal expansion at temperature T_h
- ii. adiabatic expansion to temperature T_c
- iii. isothermal compression at temperature T_c
- iv. adiabatic compression to the initial state

During step *i*, a quantity of heat Q_h flows from the reservoir at T_h into the engine. During step *iii*, a quantity of heat Q_c flows from the engine into the reservoir at T_c .

- a) Sketch the thermodynamic cycle in the usual way (p, V)-diagram. Clearly indicate the direction of the cycle. Indicate where and in which direction the engine exchanges heat and/or work with the outside world. **(8 pt)**
- b) Give the entropy change per cycle of both reservoirs in terms of the given quantities. **(8 pt)**
- c) Assume that the entropy change in the hot reservoir is exactly compensated by the entropy change in the cold reservoir. Show, that the efficiency of the cycle equals $\eta = 1 - T_c/T_h$. **(8 pt)**
- d) The coal power plant in Eemshaven produces about 12 TWh of electricity per year from about 3 million tons of coal (thermal energy content of coal: 9 kWh kg^{-1}). Determine the efficiency of the power plant and estimate T_c and T_h assuming the power plant is an idealized Carnot engine. Is the result for T_h realistic? **(6 pt)**

Constants:

Avogadro's number: $N_A = 6.02 \cdot 10^{23} \text{ mol}^{-1}$

Boltzmann constant: $k_B = 1.381 \cdot 10^{-23} \text{ J/K}$

Gas constant: $R = 8.31 \text{ J K}^{-1} \text{ mol}^{-1}$

Atomic mass unit (u): $m_u = 1.67 \cdot 10^{-27} \text{ kg}$

Electronvolt: $1 \text{ eV} = 1.6 \cdot 10^{-19} \text{ J}$
